

# JavaScript Data Type CheatSheet

## Data Type

- Data type means which type of data.
- Defines the type of variable.
- It can be number, string, boolean, etc.
- There are 2 types of data types in JS.
- Primitive data type
- Non-primitive data type

## Primitive

- Primitive values are immutable data types.
- That means it can't be changed/ altered.
- Like, string, number, bigint, boolean, null and undefined.

## String

- A string is a series of characters.
- It is a set of characters.
- It represents textual data.
- JavaScript strings are immutable.
- JavaScript strings are case-sensitive.
- That means we can't change the string.
- Must be surrounded by double or single quotes or backticks.

## number

- Represents the integer/floating numbers.
- There are also 3 special numbers in JS.
- +infinity, -infinity, NaN
- + & - infinity simple as maths.
- -infinity 0 +infinity
- NaN stands for not a number.
- 23 \* "Ajay" is NaN

## Undefined

- Which variable has no value.
- It can be a data type & a value.
- A variable without value.
- An empty variable is undefined.
- That means not initialized.

## null

- null means nothing.
- null value means there is no value.
- We can forcefully assign a "null" value to a variable for creating an empty variable.
- null = 0 = "" = nothing
- It displayed object as the data type of the "null" which is a **bug** in JavaScript.

## boolean

- It represents only two values true and false.
- Every non-zero values are true.
- All values are true except falsy values.
- Falsy values are 0, "", null, undefined, NaN & false as well.
- true = 1 = on
- false = 0 = off

## bigint

- There are 2 "number" data types in javascript.
- number and bigint data type.
- It represents the big integer value.
- Like 2134234234332423423424n

# JavaScript Variable & Operator

## Keywords

- **let** is a reserved keyword for declaring a variable.
- We can't use keywords as a name of the variable.

## Expression

- It is a combination of operators and operands.
- Returns the single value to the variable.

## Operand

- It is actual value.
- which is being manipulated using an operator is called an operand.

## Operator

- It perform actions on values or variables.
- It is used to manipulate values or variables

## Variable Name

- x is the name of the variable.
- The result of the expression is stored in the variable.
- Value is stored in a variable.

# JavaScript Loops CheatSheet

## for-in loop

👉 The **for-in** loop allows us to access the property of an object without knowing the specific name of that object's property.

👉 A different item is assigned to a variable on each iteration.

```
...  
for in loop  
  
for (const key in object) {  
    // Line of code  
}
```

👉 **key** - It's an individual key of the object that will be a variable.

👉 **object** - The object that is going to be iterated.

```
...  
example of "for in" loop  
  
let objectName = {  
    firstName: "Ajay",  
    lastName: "Yadav"  
}  
  
for (const propertyName in objectName) {  
    console.log(propertyName);  
    //firstName lastName  
    console.log(objectName[propertyName]);  
    //Ajay Yadav  
}
```

👉 We can also iterate an array using **for-in** loop.

```
...  
example of "for in" loop with an array  
  
let arr = [10, 20, 30, 40];  
for (const index in arr) {  
    console.log(index);  
    //1 2 3  
    console.log(arr[index]);  
    // 10 20 30 40
```

## for-of loop

👉 The **for-of** statement creates a loop over iterable elements like strings, arrays, or array-like elements that are NodeList, arguments, etc.

```
...  
"for of" loop  
  
for (const item of arr) {  
    //Line of code  
}
```

👉 **item** - It's an individual element of the iterable object.

👉 **arr** - It's an iterable object (array, string, NodeList, etc.) whose elements are iterated.

```
...  
Example of "for of" loop  
  
let arr = [10, 20, 30, 40, 50];  
for (const item of arr) {  
    console.log(item);  
    //10 20 30 40 50  
}
```

👉 If we omit the increase or decrease variable in the loop, then it will iterate infinitely.

```
...  
Infinite while loop  
  
let a = 0;  
while (a < 5) {  
    console.log("Hello");  
    //infinite  
}
```

👉 That's why we should use an increment or decrement variable.

```
...  
Example of while loop  
  
let a = 0;  
while (a < 5) {  
    console.log("Hello");  
    //Hello Hello Hello Hello Hello  
    a++;  
}
```

## forEach loop

👉 **forEach()** method iterates all items of an array automatically.

👉 **forEach()** method calls a function for each element in an array.

👉 This is not executed for the empty array element.

```
...  
forEach()  
  
arr.forEach(function (value, index) {  
    //Lines of code  
});
```

👉 Array elements or NodeList can be iterated using **forEach()** method.

```
...  
Examples of forEach()  
  
let arr = [10, 20, 30, 40, 50];  
  
arr.forEach(item => console.log(item));  
// 10 20 30 40 50  
  
arr.forEach(function (value, index) {  
    console.log(value);  
    //10 20 30 40 50  
    console.log(index);  
    //0 1 2 3 4  
});
```

## for loop

👉 There are 3 parts of the **for** loop.

```
...  
for loop  
  
for (initialization, condition, incre/decre) {  
    //Lines of code  
}
```

👉 **initialization** - initialization expression is executed at least one time.

👉 **condition** - It's a condition of the block of code of the **for** loop.

👉 **incre/decre** - This expression is executed after the code of the block has been executed.

👉 If we omit these expressions, then the block of code of the **for** loop will be executed infinitely.

```
...  
Infinite loop  
  
for ( ; ; ) {  
    console.log("Hello");  
    //infinite  
}
```

```
...  
for loop  
  
for (let a = 0; a < 5; a++) {  
    console.log(a);  
    //0 1 2 3 4  
}
```

## do while loop

👉 The **do while** loop is executed block of code at least once.

👉 Don't forget to add an increase or decrease variable in the loop, otherwise the loop will be iterated infinitely.

```
...  
do while loop  
  
do {  
    //Line of code  
    incre / decre;  
} while (condition);
```

```
...  
Example of do while loop  
  
let a = 0;  
do {  
    console.log(a);  
    //0 1 2 3 4  
    a++;  
} while (a < 5);
```

👉 The **do while** loop is executed at least once if the condition will be false.

```
...  
Example of do while loop  
  
let a = 2;  
do {  
    console.log(a);  
    //2  
    a++;  
} while (a < 1);
```

## NOTE

- A loop is used to iterate a block of code repeatedly until the condition is true.
- If the condition is false, then the loop will be stopped.

# Map Object CheatSheet

💡 The Map( ) object is also used to store key-value pairs but we can specify any type of primitive key-value pairs.

💡 Map( ) object is a collection of unique key-value pairs.

💡 We can create an empty Map( ) object using new and Map( ) constructor.

```
...  
Empty Map( ) Object  
  
//Create an empty Map object  
let myMap = new Map();
```

💡 Now we can add key-value pairs to the Map( ) object using 2 ways.

1. Using set( ) method.

```
...  
Adding elements to the Map( ) object  
  
//Adding the value to the Map object  
myMap.set("firstName", "Ajay");  
myMap.set(10, "num value");  
myMap.set(true, "boolean value");
```

2. Using square brackets.

```
...  
Adding elements to the Map( ) object  
  
//Adding the value to the Map object  
//using square brackets.  
let myMap = new Map(  
  [  
    ["firstName", "Ajay"],  
    [10, "num value"],  
    [true, "boolean value"],  
  ]  
);
```

💡 Once, we set the key-value pairs to the Map( ) object, provides methods that are used to manipulate Map( ) object.

💡 get( ) - Returns the value from the Map( ) object.

```
...  
Getting values  
  
//Getting the value from the Map object  
console.log(myMap.get("firstName")); //Ajay  
console.log(myMap.get(10)); //num value  
console.log(myMap.get(true)); //boolean value
```

💡 size - Returns the size of the Map( ) object.

```
...  
size of the Map( ) object  
  
// Getting the size of the Map object  
console.log(myMap.size); //3
```

💡 keys( ) - Returns the keys from the Map( ) object.

```
...  
Getting keys  
  
// Getting the keys from the Map object  
console.log(myMap.keys());  
//[Map Iterator] { 'firstName', 10, true }
```

💡 values( ) - Returns the values from the Map( ) object.

```
...  
Getting values  
  
// Getting the values from the Map object  
console.log(myMap.values());
```

💡 delete( ) - Remove the key-value pairs from the Map( ) object.

```
...  
Delete key-value pair  
  
//Deleting the key-pairs from the Map object  
myMap.delete(10); //Remove 10 and its value
```

💡 has( ) - Check the availability of the key-value pairs in the Map( ) object.

```
...  
Check the availability  
  
//Check the availability of the key-value  
//pairs in the Map() object  
console.log(myMap.has(10)); //false
```

# String Methods CheatSheet

## str.substring()

### str.slice()

- It returns nothing(empty) if the start index is bigger index.
- It treats the NaN parameter as a 0.
- When we give a -ve parameter to it then it counts backward from the end of the string to find the index.

```
slice()

let str = "Ajay Yadav";
console.log(str.slice()); //Ajay Yadav
console.log(str.slice(0, 4)); //Ajay
console.log(str.slice(0, -4)); //Ajay Y
console.log(str.slice(NaN, 4)); //Ajay
console.log(str.slice(-5)); //Yadav
console.log(str.slice(9, -3)); //Nothing (9 > 3)
console.log(str.slice(-5, -1)); //Yada
console.log(str.slice(1, -5)); //Nothing(-1 > -5)
console.log(str.slice(NaN, -5)); //Ajay
console.log(str.slice(-4, 6)); //Nothing
```

### str.trim()

- The trim() method is used to remove whitespace from both ends of the string.
- To remove whitespace from the beginning and from the end of the string then we can use trimStart() & trimEnd() methods respectively.

```
trim()

let str = " Ajay ";
console.log(str.trim()); //Ajay
console.log(str.trimEnd()); // Ajay
console.log(str.trimStart()); //Ajay
```

### str.toLowerCase()

- This method is used to convert all string characters into lowercase letters.
- If the string is undefined or null then we'll get an error.

```
toLowerCase()

let str = "AJAY YADAV";
console.log(str.toLowerCase());
//ajay yadav
console.log(test.toLowerCase());
//Error
```

### str.startsWith()

- It returns true if a string starts with a specified string, otherwise returns false.

```
startsWith()

let str = "Ajay Yadav";
console.log(str.startsWith("A")); //true
console.log(str.startsWith("Ajay")); //true
console.log(str.startsWith("AJAY")); //false
console.log(str.startsWith("Y", 5)); //true
console.log(str.startsWith("Y", 4)); //false
```

### str.repeat()

- It returns the copied versions of the original string.
- We can pass an integer number between 0 and +infinity times to repeat the string.
- If we pass the -ve number, then we will get "RangeError" as an output.
- Also, if we pass a fractional number, then it will round a number down to the nearest integer.

```
repeat()

let str = "Ajay";
console.log(str.repeat(5)); // Repeat 5 times
console.log(str.repeat(4.5)); // Repeat 4 times
console.log(str.repeat(0)); // Repeat 0 times
console.log("-".repeat(10)); // ++++++++
console.log(str.repeat(-5)); //RangeError
```

### str.replaceAll()

- This method is recently added ES2021 version of JavaScript.
- It replaces all occurrences of a substring with a new string.
- Substring is a part of the original string.

```
replaceAll()

let str = "You are awesome";
console.log(str.replaceAll(" ")); //["You", 'are', 'awesome']
console.log(str.replaceAll(" ", 2)); //["You", 'are']
console.log(str.replaceAll(""));
// [ 'Y', 'o', 'u', ' ', 'a', 'r', 'e', ' ', 'a', 'w', 'e', 's', 'o', 'm', 'e' ]
```

### str.indexOf()

- It is used to find the index of a substring within a string.
- Keep in mind that it returns the index of the first occurrence of a substring within a string.
- And returns (-1) if the argument doesn't exist in the string.

```
indexOf()

let str = "Ajay Yadav";
console.log(str.indexOf("a")); //2
console.log(str.indexOf("A")); //0
console.log(str.indexOf("D")); //-1 (Not exist)
```

### str.charCodeAt()

- It returns the Unicode(ASCII) of the character in a string.

```
charCodeAt()

console.log("A".charCodeAt()); //65
console.log("a".charCodeAt()); //97
console.log(" ".charCodeAt()); //32
console.log("Z".charCodeAt()); //90
console.log("z".charCodeAt()); //122
```

### NOTE

- Searching values that will be passed to string methods are case-sensitive.

String methods don't change the original string because the string is the immutable data type.

- If the start parameter is greater than the end parameter then it swaps that parameters.
- It treats the negative parameter as 0.

```
substring()

let str = "Ajay Yadav";
console.log(str.substring()); //Ajay Yadav
console.log(str.substring(0, 4)); //Ajay
console.log(str.substring(0, -4)); //Nothing
console.log(str.substring(NaN, 4)); //Ajay
console.log(str.substring(-5)); //Nothing
console.log(str.substring(9, 3)); //yada
console.log(str.substring(-5, -1)); //Nothing
console.log(str.substring(1, -5)); //Nothing
console.log(str.substring(NaN, -5)); //Nothing
console.log(str.substring(-4, 6)); //Ajay Y
```

## str.concat()

- The concat() method is used to merge two or more strings and returns a new string.
- We can join multiple string like str.concat(str1, str2, str3, ... strN);

```
concat()

let firstName = "Ajay";
let lastName = 'Yadav';
console.log(firstName.concat(lastName));
//AjayYadav
console.log(firstName.concat(" " + lastName));
// Ajay Yadav
```

## str.toUpperCase()

- This method is used to convert all string characters into uppercase letters.
- If the string is undefined or null then we'll get an error.

```
toUpperCase()

let str = "ajay yadav";
console.log(str.toUpperCase());
//AJAY YADA
console.log(test.toUpperCase());
//Error
```

## str.endsWith()

- It returns true if a string ends with a specified string, otherwise returns false.

```
endsWith()

let str = "Ajay Yadav";
console.log(str.endsWith("v")); //true
console.log(str.endsWith("Yadav")); //true
console.log(str.endsWith("V")); //false
console.log(str.endsWith("YADA")); //false
console.log(str.endsWith("yadaV", 5)); //false
```

## str.lastIndexOf()

- It is used to find the last occurrence of a substring within a string.
- It also returns (-1) if the substring doesn't exist within a string.

```
lastIndexOf()

let str = "Ajay Yadav";
console.log(str.lastIndexOf()); // -1 (Not exist)
console.log(str.lastIndexOf("Ajay")); //0
console.log(str.lastIndexOf("Yadav")); //5
```

## str.fromCharCode()

- This method converts Unicode values to characters.
- It returns a primitive string and not an object string.
- You always use it as "String.fromCharCode()".

```
fromCharCode()

console.log(String.fromCharCode(65)); //A
console.log(String.fromCharCode(74)); //Y
console.log(String.fromCharCode(89)); //Y
console.log(String.fromCharCode(65, 74, 65, 89)); //AJAY
```

## str.padEnd()

- It is used to insert(pad) a string with another string to a certain length to the end of the string and returns a resulting string.

```
padEnd()

let str = "Ajay";
console.log(str.padEnd(10, "."));
//Ajay.....
console.log(str.padEnd(3, "."));
//Ajay
```

## str.padStart()

- It is used to insert(pad) a string with another string to a certain length from the start of the string and returns a resulting string.

```
padStart()

let card = "1234";
console.log(card.padStart(16, "x"));
//xxxxxxxxxxxxxx1234
console.log(card.padStart(2, "x"));
//1234
```
